Q2) A SW company with CMM=1 is hired on a project team yet, along perfectly well the comp. is totally familiar with the app. there is no client involvement, a very through risk analysis has been implemented

a) Given that 17 attributes are considered in estimating the SW effort, what COCOMO II model is used to estimate the effort

b) Calculate the exponent term β considering the first sentence of the question

c) At the end of the project, SW effort estimated, E_{est}, is found to be 20% less than the actual effort, E_{act}) ($e_E = \{|E_{act} - E_{est}|\} / E_{act} * 100 = 20\%$)

Given that $E = A * size^B * M$ and $M_{est} = 0,85\, M_{act}$, what is the percentage error, else, in the SW size?

Hint: e_E denotes the percent error in effort, A and M denote, in respective order the constant factor and multipliers. (C45)

Q3) a) Is the statement "Cookies are a type of distributed DBMS" correct? why

b) Cookies can keep the state of the client at the client side. What are two disadvantages of using cookies this way?

c) How should cookies be used to avoid the disadvantages you discussed in part b.

1 only Question"

Yours Enric Fortuny

Q2) a) Algorithmic Cost Modeling.

b) $\frac{CMM=1}{5-1=4}$ $\left(\frac{(4+0+0+0+5)}{100}\right)+1,01 = 0,09+1,01$

$= 1,1 \Rightarrow B$

c) $A=2,94$

$Effort = A * Size^{1,1} * Most$

$Eact = A \times Size^{1,1}act * Mact$

$Eest = \frac{80}{100} \times Eact$

$= \left(\frac{Sizeest}{Sizeact}\right)^{1,1} \times 0,85 = 0,8$

$Mest = 0,55 Mact$

$\left(\frac{SizeEst}{SizeAct}\right)^{1,1} = 0,961$

Q3) a) In terms of keeping informations of user, we can say cookies are type of DBMS. (Answer = Yes) (15)

b) In the case of hacking, hackers can reach user informations via site. Cookies can make our computers slower in terms of size problem.

c) Critical user informations should not keep in these cookies (password & credit card)
Cookies must be cleaned in periodic time.
